

Tool wear is invisible until it isn't.

From spindle telemetry to a tool-change decision.

Metrik reads live spindle telemetry, scores wear and risk with two independently validated models grounded in machining physics, explains every number, and hands the decision to the operator.

Every endpoint is read-and-recommend — Metrik never stops, throttles, or reconfigures a machine.

Two models, kept deliberately separate.

A working, end-to-end application.

UI reconstructed from the project's real React components (MachineCard.jsx, GaugeChart.jsx) and live values from its own demo fleet.

Not "we use AI" — a specific, defensible combination.

Who it helps, and what it changes.

DEMONSTRATED

+19.3% Tool Life Recovered

Vs. a practical fixed schedule, in offline validation across three cutters — zero tools changed late.

EXPECTED

Operators Act on Evidence

A live, explained wear reading at the machine replaces a calendar guess.

EXPECTED

Waste Cut in Both Directions

Fewer scrapped parts from undetected wear, fewer tools discarded with life left in them.

POTENTIAL

Accessible to Small Shops

Standard telemetry, no proprietary sensor hardware — scales down-market where vendor suites can't.

POTENTIAL

Fleet-Wide Visibility

Plant managers plan maintenance windows around production, not around failures.

Where this stands, and where it goes.

Metrik doesn't ask a shop to trust a black box — it grounds a wear estimate in physics, explains every number, and reports its own validation honestly enough to survive scrutiny.
